

## AVOGADRO'S HYPOTHESIS - SAMPLE PROBLEMS

### KEY

PLEASE NOTE THAT  $N_a$  = Avogadro's number =  $6.02 \times 10^{23}$  molecules

1. There are  $3.67 \times 10^{32}$  molecules of nitrogen gas in a flask at STP.  
How many molecules of oxygen gas would be present in the same flask?  
 $3.67 \times 10^{32}$  molecules of oxygen gas.  
From Avogadro's Hypothesis, we have learned that the number of moles (or molecules) of the gas in a sample at a given volume, temperature, and pressure does NOT depend on the identity of the gas.
2. 312 L of chlorine gas at STP. What mass of fluorine gas would be present at the same volume, temperature and pressure.  
 $312 \text{ L} \times 1 \text{ mole} / 22.4 \text{ L} \times 38.0 \text{ g} / \text{mole} = 529 \text{ g}$   
2b. How many molecules would this be?  
 $13.9 \text{ mole} \times N_a = 8.37 \times 10^{24}$  molecules
3. What mass do  $4.37 \times 10^{32}$  molecules of ammonia gas possess?  
 $4.37 \times 10^{32}$  molecules  $\times N_a \times 17.0 \text{ g} / \text{mole} = 1.23 \times 10^{10} \text{ g}$
4. 156 g of ammonia gas in a flask at STP. What mass of chlorine gas would fit in the same flask?  
 $156 \text{ g} \times 1 \text{ mole} / 17.0 \text{ g} = 9.18 \text{ moles}$   
AVOGADRO'S HYPOTHESIS:  
(V, T, P)  $\text{NH}_3 = (\text{V}, \text{T}, \text{P}) \text{Cl}_2$   
# of molecules of  $\text{NH}_3 = \#$  of molecules of  $\text{Cl}_2$   
moles of  $\text{NH}_3 = \text{moles of } \text{Cl}_2$   
 $9.18 \text{ moles} \times 71.0 \text{ g} / \text{mole} = 651 \text{ g}$
5. 211.5 g of fluorine gas at RTP. 178 g of oxygen gas in the same container at RTP. How many litres of each gas are present at RTP?  
 $211.5 \text{ g} \times 1 \text{ mole} / 38.0 \text{ g} \times 24.5 \text{ L} / \text{mole} = 136 \text{ L } \text{F}_2$   
 $178 \text{ g} \times 1 \text{ mole} / 32.0 \text{ g} \times 24.5 \text{ L} / \text{mole} = 136 \text{ L } \text{O}_2$   
Due to Avogadro's hypothesis, the volume that both gases occupy will be equal, since the temperature and pressure conditions are the same, and the # of moles is the same. (Check it! The number of moles of both gases is 5.57 moles)

6. A balloon holds 4678 g of He gas. What mass of hydrogen gas would it hold at identical conditions?

$$4678 \text{ g} \times 1 \text{ mole} / 4.00 \text{ g He} \times 2.02 \text{ g H}_2 / \text{mole} = 2.36 \times 10^3 \text{ g}$$

$$(V, T, P) \text{ He} = (V, T, P) \text{ H}_2$$

$$\text{moles of He} = \text{moles of H}_2$$

7. What mass of Neon gas would the balloon in #6 hold (at identical conditions)?

$$1169.5 \text{ moles (from question 6)} \times 20.2 \text{ g Ne} / \text{mole} = 2.36 \times 10^4 \text{ g}$$

7b. How do the molecules of hydrogen gas and Neon gas compare in mass?

$$\frac{2.36 \times 10^4 \text{ g Ne}}{2.36 \times 10^3 \text{ g H}_2} = 10.0$$

$$2.36 \times 10^3 \text{ g H}_2$$

$$\text{mass of Ne} : \text{mass of H}_2 = 10 : 1 \text{ ratio}$$

i.e. Neon gas' mass is 10 times the hydrogen gas' mass

8. How many molecules of carbon monoxide gas are present in 176 L of the gas at STP?

$$176 \text{ L} \times 1 \text{ mol} / 22.4 \text{ L} \times N_a = 4.73 \times 10^{24} \text{ CO molecules}$$

9. A container holds 6.93 moles of ammonia gas at 42°C and 176 kPa. What mass of chlorine gas would the container hold at identical conditions?

$$6.93 \text{ moles} \times 71.0 \text{ g} / \text{mole} = 491 \text{ g Cl}_2$$

10. A container holds 302 g of gas "X". The same container holds 75 g of oxygen gas under identical conditions. What is the molar mass of gas "X"?

$$75 \text{ g} \times 1 \text{ mole} / 32.0 \text{ g O}_2 = 2.3 \text{ moles}$$

$$\frac{302 \text{ g of gas "X"}}{2.3 \text{ moles}} = 131.3 \text{ g} / \text{mole} \quad \text{must be Xe}$$

$$2.3 \text{ moles}$$

11. Argon has a density of 1.784 g/L.

How many atoms are present in 220. mL of Argon gas?

$$0.22 \text{ L} \times 1.784 \text{ g} / \text{L} \times 1 \text{ mole} / 39.9 \text{ g Ar} \times N_a = 5.91 \times 10^{21} \text{ Ar atoms}$$

12. 361 L of C<sub>3</sub>H<sub>8</sub> gas at STP. How many moles would exist at RTP?

$$361 \text{ L} \times 1 \text{ mole} / 22.4 \text{ L} \times 24.5 \text{ L} / \text{mole} = 395 \text{ L}$$

We know to divide by STP and multiply by RTP

Since the temperature is going up, we expect the volume of the gas to get BIGGER.
